This document contains the following supporting information:

S1. Chemicals

S2. Chemical Analysis

S3. Potential source contribution function (PSCF)

Table S1. DTT_v activity normalized by volume (nmol/min/m³)

Table S2. DTT_m activity normalized by PM mass (nmol/min/μg).

Table S3. Average DTT_v (nmol/min/m³) and DTT_m (pmol/min/μg) of water-soluble extracts from ambient PM_{2.5} at different locations all over the world.

Table S4. The seasonal variation of TFV (R.U.nm²) of four chromophores.

Table S5. Regression equations of ·DTT loss rate from individual metals.

Table S6. Seasonal variation of chemical composition concentration of WSM (WSOC, OC, EC, and ions μg/m³, elements, ng/m³).

Table S7. Spearman correlation coefficient (r) of DTT activity with chemical composition of PM_{2.5}.

Figure S1. (A) Dithiothreitol (DTT) oxidation by redox active species in PM with subsequently ROS formation. (B) DTT reaction with 5,5'-dithio-bis (2-nitrobenzoic acid) (DTNB).

Figure S2. Seasonal variations of potential source regions for water-soluble DTT_v in Shanghai PM_{2.5} (based on 48h backward trajectory).

Figure S3. Seasonal variations in the DTT consumption rate. DTT_v is the DTT consumption rate per cubic meter of atmospheric volume. DTT_m is the DTT consumption rate per microgram of PM_{2.5}.

Figure S4. Average DTT_v (nmol/min/m³) and DTT_m (pmol/min/μg) of water-soluble extracts from ambient PM_{2.5} at different locations in China (A) and (B) other countries all over the world.

Figure S5. The frequency distributions of the Pearson's correlation coefficients between different sample EEMs are calculated from the EEM pixel data points of the WSM and MSM.

Figure S6. Error comparison of C3 – C6 model results in PARAFAC analysis. The bold green dotted line indicates the number of factors selected in the study.

Figure S7. Split-half validation of the four-component model. Spectra were derived from two independent models of fluorescence EEM from two randomly split halves (with respect to samples) and matched to similar components in the model of the entire data set. The solid and dashed lines represent the spectra against excitation and emission wavelengths respectively.

Figure S8. (A) Relative contributions of four components to the total fluorescent volume. (B) Relative contributions of the fluorescent volumes of the WSM and MSM.

Figure S9. DTT loss rates as a function of concentration of individual metals. Lines represent regression fits to the experimental data; and the error bar represent the 95% confidence interval of DTT activity.

S1. Chemicals

The following chemicals were purchased from Sigma-Aldrich (Shanghai, China): sodium phosphate monobasic (NaH₂PO₄), sodium phosphate dibasic (Na₂HPO₄), DL-Dithiothreitol (DTT, 99.0%), 5,5'-dithiobis (2-nitrobenzoic acid) (DTNB, ReagentPlus, 99%), tris (hydroxymethyl) aminomethane (Tris, ACS reagent, 99.8%), ethylenediaminetetraacetic acid (EDTA, 99.995%), trischloroacetic acid (TCA, ACS reagent, 99.0%), methanol (MeOH). Nitric acid (HNO₃, 69%) and hydrofluoric acid (HF, 49%) were from Tansoole (Shanghai, China).

S2 UV-visible absorption spectra and EEM fluorescence spectra

The UV-visible absorption spectra of extracts were measured by Microplate Reader (BioTek Synergy™ HTX, Vermont, USA) between 200 and 800 nm with an interval of 5 nm in a 96-well quartz plate. The light absorption coefficient of the extracts at a given wavelength (Abs_{λ} , Mm⁻¹) can be calculated using eq1:

$$Abs_{\lambda} = (A_{\lambda} - A_{700}) \times \frac{V_{\text{extraction}}}{V_{\text{air}} \cdot l} \times \ln(10) \quad (1)$$

where $V_{\text{extraction}}$ (mL) is the volume of the extraction, V_{air} (m³) related to the volume of air sampled through the filter during the sampling, l (cm) was the path length of light. A_{λ} at all wavelengths is referenced to A_{700} to account for systematic baseline drift.

The absorption Angstrom exponent (AAE) for each extract was an important parameter to describe the dependency of extracts' optical thickness on wavelength. It can be calculated using the Abs values between wavelength λ_1 and λ_2 (eq2):

$$AAE = \ln\left(\frac{Abs_{\lambda_1}}{Abs_{\lambda_2}}\right) / \ln\left(\frac{\lambda_2}{\lambda_1}\right) \quad (2)$$

The excitation-emission matrix (EEM) spectra were measured using an Aqualog fluorimeter (Horiba-Jobin Yvon, Japan). The EEMs were measured in the range from 240 to 550 nm for excitation using 2 nm intervals and from 250 to 600 nm for emission at 3 nm intervals. The intensity of all EEM spectra was normalized by the area of the Raman water line obtained at 350 nm excitation and 397 nm emission wavelengths; the data were processed with inner-filter correction and Rayleigh scattering elimination. The EEM spectra were calibrated with Quinine sulfate standards, and the fluorescence intensities were expressed in units of quinine sulfate equivalents (QSE) (Coble, 1996). The fluorescence volume (FV, R.U.nm²) of PM extracts was calculated using

fluorescence regional integration (FRI) (eq3) (Chen et al., 2003).

$$FV = \sum_{\text{ex}} \sum_{\text{em}} I(\lambda_{\text{ex}} \lambda_{\text{em}}) \Delta \lambda_{\text{ex}} \Delta \lambda_{\text{em}} \quad (3)$$

S3. Chemical Analysis

Organic carbon (OC) and elemental carbon (EC) concentration of each sample were analysis by using a thermal/optical carbon analyzer (DRI Model 2001A, Atmoslytic Inc., Calabasas, CA, USA). A more detailed description of the analytical methods and calibration procedures are available in earlier paper(Feng et al., 2012). The water-soluble organic carbon (WSOC) was measured by total organic carbon analyzer (TOC-V CPH, Shimadzu, Japan). Water-soluble inorganic ions (Na^+ , NH_4^+ , K^+ , Mg^{2+} , Ca^{2+} , Cl^- , NO_3^- , and SO_4^{2-}) were analyzed by ion chromatography (ICS-2000 and ICS-2500, DIONEX). Water-soluble metal (Pb, Mn, Zn, K, Cr, Fe, Ti, Sr, Al, Ca, Br, Ba, and Zr) in the particle samples were analyzed by using 7900 ICP-MS instrument (Agilent Technologies). Briefly, each samples were sonicated in 2mL of DI water for 1 h, after sonication, the extracts were filtered using PTFE 0.45 μm pore syringe filters, then HNO_3 was added to produce a final concentration of 2% before ICP-MS (7900, Agilent Technologies) determination. In this study, we focus on Cu, Fe, and Mn as they are common redox active species linked to particle-generated $\cdot\text{OH}$. The signal response of a series of standard metal solutions (0.1-100 ppb) was recorded and the R^2 of the standard calibration curves ranged from 0.9991 to 0.9998 ($N = 6$) for the target metals.

S4. Potential source contribution function (PSCF)

PSCF modeling (Ashbaugh et al., 1985) was used to locate potential source areas contributing to the DTT activity. PSCF, defined as the conditional probability that the air mass reaching the receptor site after transport has a pollutant concentration above the given criterion, is given by

$$\text{PSCF}_{ij} = \frac{m_{ij}}{n_{ij}} \quad (1)$$

where n_{ij} is the total number of trajectory endpoints that fall in the ij_{th} grid cell during transportation to the receptor site, and m_{ij} is a subclass of n_{ij} whose trajectory endpoints are associated with the pollutant concentrations higher than the given criterion. The grid cells with high PSCF_{ij} indicate regions of 'high potential'

contribution for the pollutant. Generally, $PSCF_{ij}$ values < 0.5 are considered to be low, whereas values of 0.5–1.0 are considered high.

To minimize high uncertainties caused by small n_{ij} values, a weighting function W_{ij} was applied to constrain the contribution from grids with a low number of trajectories. Based on the mean number of trajectory endpoints in each grid (n_{ave}), the weighting function W_{ij} (Polissar et al., 2001) is defined as

$$W_{ij} = \begin{cases} 1.00 & 3n_{ave} < n_{ij} \\ 0.70 & 1.5n_{ave} < n_{ij} < 3n_{ave} \\ 0.42 & 0.75n_{ave} < n_{ij} < 1.5n_{ave} \\ 0.17 & n_{ij} < 0.75n_{ave} \end{cases} \quad (4)$$

In PSCF analysis, a 48-h backward trajectory was calculated every 4 h to identify potential regional contributions of DTT_v . The analysis was initiated at an altitude of 500 m. The geophysical regions covered by the trajectories were split into $0.5^\circ \times 0.5^\circ$ grid cells.

Ca	31.99	7.97	73.45	33.26	95.53	113.06	56.96	27.30

Table S7. Spearman's correlation coefficient (r) between DTT_v and PM_{2.5} components.

	DTT _v (WSM)	DTT _v (MSM)
WSOC	0.80**	0.61**
OC	0.85**	0.47*
EC	0.87**	0.43*
Cl ⁻	0.59**	0.02
Br ⁻	0.63**	0.62**
NO ₃ ⁻	0.84**	0.41*
SO ₄ ²⁻	0.87**	0.48*
PO ₄ ²⁻	0.10	-0.33
Na ⁺	0.27	-0.12
NH ₄ ⁺	0.86**	0.50*
K ⁺	0.81**	0.30
Ca ²⁺	-0.26	-0.25
Mg ²⁺	-0.55	-0.46*
V	0.33	0.40
Mn	0.92**	0.49*
Cu	0.61**	0.40
Fe	0.53**	0.33
Co	0.25	0.35
Mg	-0.29	-0.07
Al	0.16	0.18
Ca	-0.29	-0.03

** Correlation is significant at 0.01 level (2-tailed).

* Correlation is significant at 0.05 level (2-tailed).

Figure S1. (A) Dithiothreitol (DTT) oxidation by redox active species in PM with subsequently ROS formation. (B) DTT reaction with 5,5'-dithio-bis (2-nitrobenzoic acid) (DTNB).

Figure S2. Seasonal variations of potential source regions for water-soluble DTT_v in Shanghai PM_{2.5} (based on 48h backward trajectory).

Figure S3. Seasonal variations in the DTT consumption rate. DTT_v is the DTT consumption rate per cubic meter of atmospheric volume. DTT_m is the DTT consumption rate per microgram of PM_{2.5}.

Figure S4. Average DTT_v (nmol/min/m³) and DTT_m (pmol/min/μg) of water-soluble extracts from ambient PM_{2.5} at different locations in China (A) and (B) other countries all over the world.

Figure S5. The frequency distributions of the Pearson's correlation coefficients between different sample EEMs are calculated from the EEM pixel data points of the WSM and MSM.

Figure S6. Error comparison of C3 – C6 model results in PARAFAC analysis. The bold green dotted line indicates the number of factors selected in the study.

Figure S7. Split-half validation of the four-component model. Spectra were derived from two independent models of fluorescence EEM from two randomly split halves (with respect to samples) and matched to similar components in the model of the entire data set. The solid and dashed lines represent the spectra against excitation and emission wavelengths respectively.

Figure S8. (A) Relative contributions of four components to the total fluorescent volume. (B) Relative contributions of the fluorescent volumes of the WSM and MSM.

Figure S9. DTT loss rates as a function of concentration of individual metals. Lines represent regression fits to the experimental data; and the error bar represent the 95% confidence interval of DTT activity.
